

Lecture 21

# **EECS 483: COMPILER CONSTRUCTION**

# Announcements

- HW5: OAT v. 2.0
  - Fully released now
  - Due on Friday, April 12
- Guest lectures
  - Lectures on Optimization and Dataflow analysis – Eric
  - After that TBA
  - No class on April 8 (eclipse)

# **CODE ANALYSIS**

# Liveness information

- Consider this program:

```
int f(int x) {  
    int a = x + 2;  
    int b = a * a;  
    int c = b + x;  
    return c;  
}
```

← x is live

← a and x are live

← b and x are live

← c is live

- The scopes of a,b,c,x all overlap – they're all in scope at the end of the block.
- But, a, b, c are never live at the same time.
  - So they can share the same stack slot / register

# Live Variable Analysis

- A variable  $v$  is *live* at a program point if  $v$  is defined before the program point and used after it.
- Liveness is defined in terms of where variables are *defined* and where variables are *used*
- Liveness analysis: Compute the live variables between each statement.
  - May be *conservative* (i.e. it may claim a variable is live when it isn't) so because that's a safe approximation
  - To be useful, it should be more *precise* than simple scoping rules.
- Liveness analysis is one example of *dataflow analysis*
  - Other examples: Available Expressions, Reaching Definitions, Constant-Propagation Analysis, ...

# Control-flow Graphs Revisited

- For the purposes of dataflow analysis, we use the *control-flow graph* (CFG) intermediate form.
- Recall that a basic block is a sequence of instructions such that:
  - There is a distinguished, labeled entry point (no jumps into the middle of a basic block)
  - There is a (possibly empty) sequence of non-control-flow instructions
  - The block ends with a single control-flow instruction (jump, conditional branch, return, etc.)
- A *control flow graph*
  - Nodes are blocks
  - There is an edge from B1 to B2 if the control-flow instruction of B1 might jump to the entry label of B2
  - There are no “dangling” edges – there is a block for every jump target.

Note: the following slides are intentionally a bit ambiguous about the exact nature of the code in the control flow graphs:

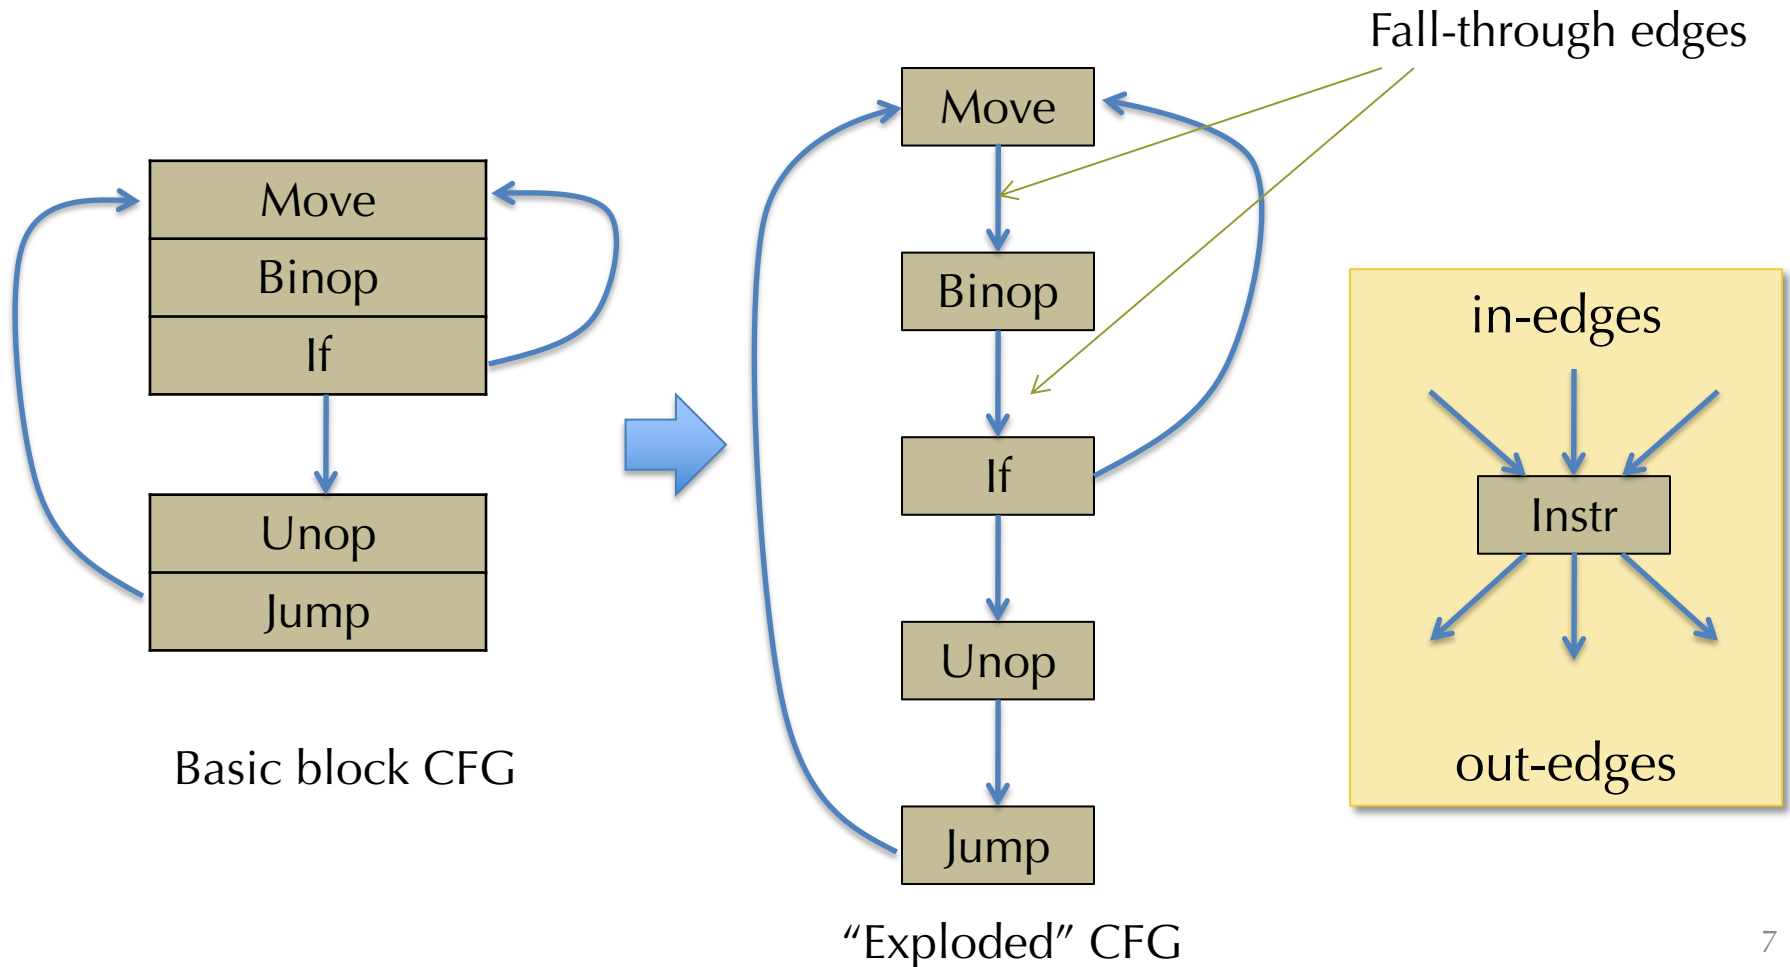

an “imperative” C-like source level  
at the x86 assembly level  
the LLVM IR level

Each setting applies the same general idea, but the exact details will differ.

- e.g., LLVM IR doesn’t have “imperative” update of %uid temporaries.  
(The SSA structure of the LLVM IR (by design!) makes some of these analyses simpler.)

# Dataflow over CFGs

- For precision, it is helpful to think of the “fall through” between sequential instructions as an edge of the control-flow graph too.
  - Different implementation tradeoffs in practice...

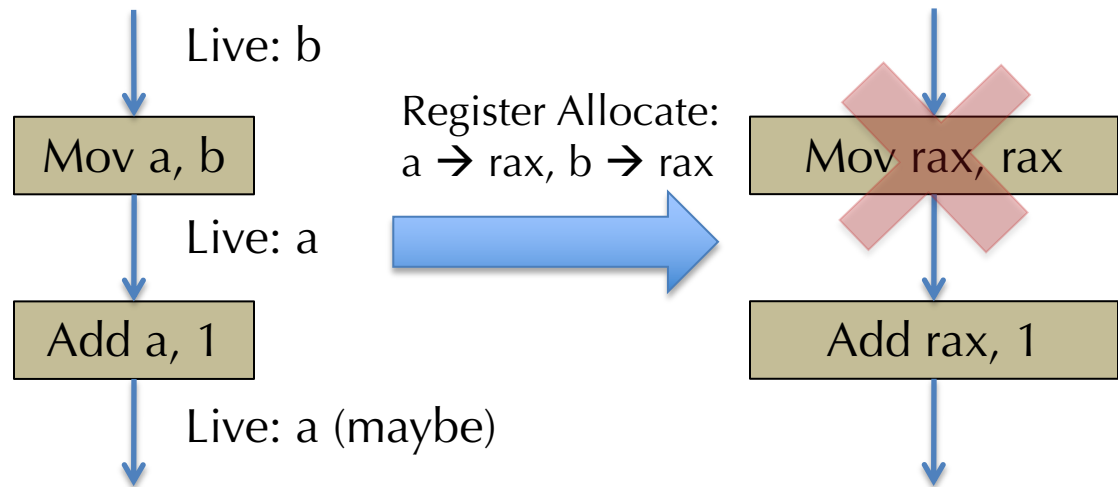

# Liveness is Associated with *Edges*

- This is useful so that the same register can be used for different temporaries in the same statement.
- Example:  $a = b + 1$

- Compiles to:

# Uses and Definitions

- Every instruction/statement *uses* some set of variables
  - i.e. reads from them
- Every instruction/statement *defines* some set of variables
  - i.e. writes to them
- For a node/statement  $s$  define:
  - $use[s]$  : set of variables used by  $s$
  - $def[s]$  : set of variables defined by  $s$
- Examples:
  - $a = b + c$        $use[s] = \{b, c\}$        $def[s] = \{a\}$
  - $a = a + 1$        $use[s] = \{a\}$        $def[s] = \{a\}$

# Liveness, Formally

- A variable  $v$  is *live* on edge  $e$  if:  
There is
  - a node  $n$  in the CFG such that  $\text{use}[n]$  contains  $v$ , and
  - a directed path from  $e$  to  $n$  such that for every statement  $s'$  on the path,  $\text{def}[s']$  does not contain  $v$
- The first clause says that  $v$  will be used on some path starting from edge  $e$ .
- The second clause says that  $v$  won't be redefined on that path before the use.
- Questions:
  - How to compute this efficiently?
  - How to use this information (e.g. for register allocation)?
  - How does the choice of IR affect this?  
(e.g. LLVM IR uses SSA, so it doesn't allow redefinition  $\Rightarrow$  simplify liveness analysis)

# Simple, inefficient algorithm

- “A variable  $v$  is live on an edge  $e$  if there is a node  $n$  in the CFG using it *and* a directed path from  $e$  to  $n$  passing through no def of  $v$ .”
- Backtracking Algorithm:
  - For each variable  $v$ ...
  - Try all paths from each use of  $v$ , tracing backwards through the control-flow graph until either  $v$  is defined or a previously visited node has been reached.
  - Mark the variable  $v$  live across each edge traversed.
- Inefficient because it explores the same paths many times (for different uses and different variables)

# Dataflow Analysis

- *Idea*: compute liveness information for all variables simultaneously.
  - Keep track of sets of information about each node
- *Approach*: define *equations* that must be satisfied by any liveness determination.
  - Equations based on “obvious” constraints.
- Solve the equations by iteratively converging on a solution.
  - Start with a “rough” approximation to the answer
  - Refine the answer at each iteration
  - Keep going until no more refinement is possible: a *fixpoint* has been reached
- This is an instance of a general framework for computing program properties: dataflow analysis

# Dataflow Value Sets for Liveness

- Nodes are program statements, so:
- $use[n]$  : set of variables used by  $n$
- $def[n]$  : set of variables defined by  $n$
- $in[n]$  : set of variables live on entry to  $n$
- $out[n]$  : set of variables live on exit from  $n$
- Associate  $in[n]$  and  $out[n]$  with the “collected” information about incoming/outgoing edges
- For Liveness: what constraints are there among these sets?
- Clearly:  
$$in[n] \supseteq use[n]$$
- What other constraints?

# Other Dataflow Constraints

- We have:  $\text{in}[n] \supseteq \text{use}[n]$ 
  - “A variable must be live on entry to  $n$  if it is used by  $n$ ”
- Also:  $\text{in}[n] \supseteq \text{out}[n] - \text{def}[n]$ 
  - “If a variable is live on exit from  $n$ , and  $n$  doesn’t define it, it is live on entry to  $n$ ”
  - Note: here ‘-’ means “set difference”
- And:  $\text{out}[n] \supseteq \text{in}[n']$  if  $n' \in \text{succ}[n]$ 
  - “If a variable is live on entry to a successor node of  $n$ , it must be live on exit from  $n$ .”

# Iterative Dataflow Analysis

- Find a solution to those constraints by starting from a rough guess.
  - Start with:  $\text{in}[n] = \emptyset$  and  $\text{out}[n] = \emptyset$
- The guesses don't satisfy the constraints:
  - $\text{in}[n] \supseteq \text{use}[n]$
  - $\text{in}[n] \supseteq \text{out}[n] - \text{def}[n]$
  - $\text{out}[n] \supseteq \text{in}[n']$  if  $n' \in \text{succ}[n]$
- Idea: iteratively re-compute  $\text{in}[n]$  and  $\text{out}[n]$  where forced to by the constraints.
  - Each iteration will add variables to the sets  $\text{in}[n]$  and  $\text{out}[n]$  (i.e. the live variable sets will increase monotonically)
- We stop when  $\text{in}[n]$  and  $\text{out}[n]$  satisfy these equations: (which are derived from the constraints above)
  - $\text{in}[n] = \text{use}[n] \cup (\text{out}[n] - \text{def}[n])$
  - $\text{out}[n] = \bigcup_{n' \in \text{succ}[n]} \text{in}[n']$

# Complete Liveness Analysis Algorithm

```
for all n, in[n] :=  $\emptyset$ , out[n] :=  $\emptyset$ 
repeat until no change in 'in' and 'out'
  for all n
    out[n] :=  $\bigcup_{n' \in \text{succ}[n]} \text{in}[n']$ 
    in[n] := use[n]  $\cup$  (out[n] - def[n])
  end
end
```

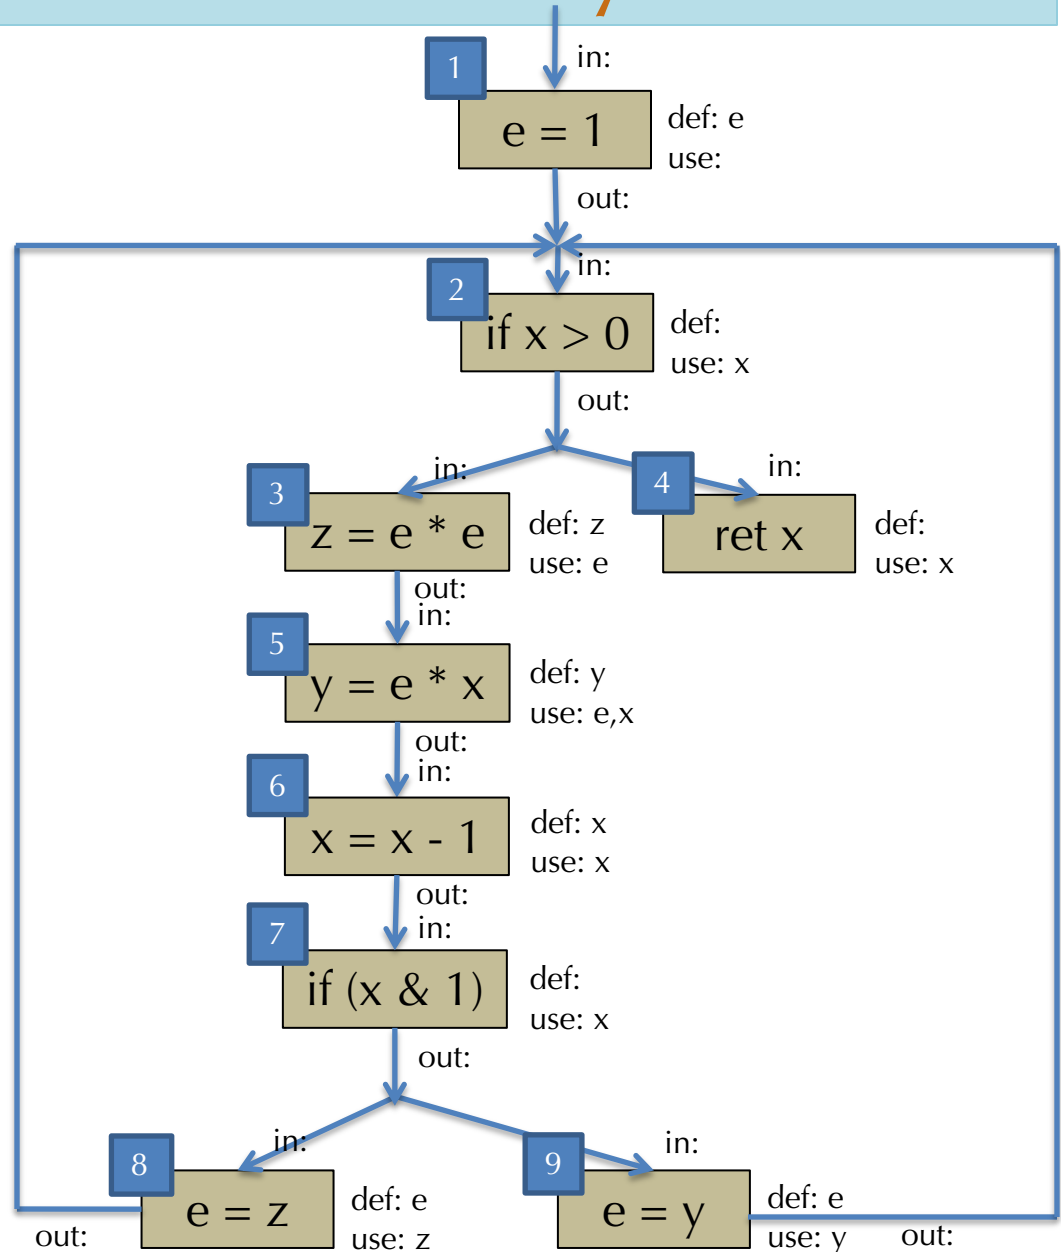

- Finds a *fixpoint* of the **in** and **out** equations.
  - The algorithm is guaranteed to terminate... Why?
- Why do we start with  $\emptyset$ ?

# Example Liveness Analysis

- Example flow graph:

```
e = 1;
while(x>0) {
  z = e * e;
  y = e * x;
  x = x - 1;
  if (x & 1) {
    e = z;
  } else {
    e = y;
  }
}
return x;
```

# Example Liveness Analysis

Each iteration update:

$$\text{out}[n] := \bigcup_{n' \in \text{succ}[n]} \text{in}[n']$$

$$\text{in}[n] := \text{use}[n] \cup (\text{out}[n] - \text{def}[n])$$

- Iteration 1:

in[2] = x

in[3] = e

in[4] = x

in[5] = e, x

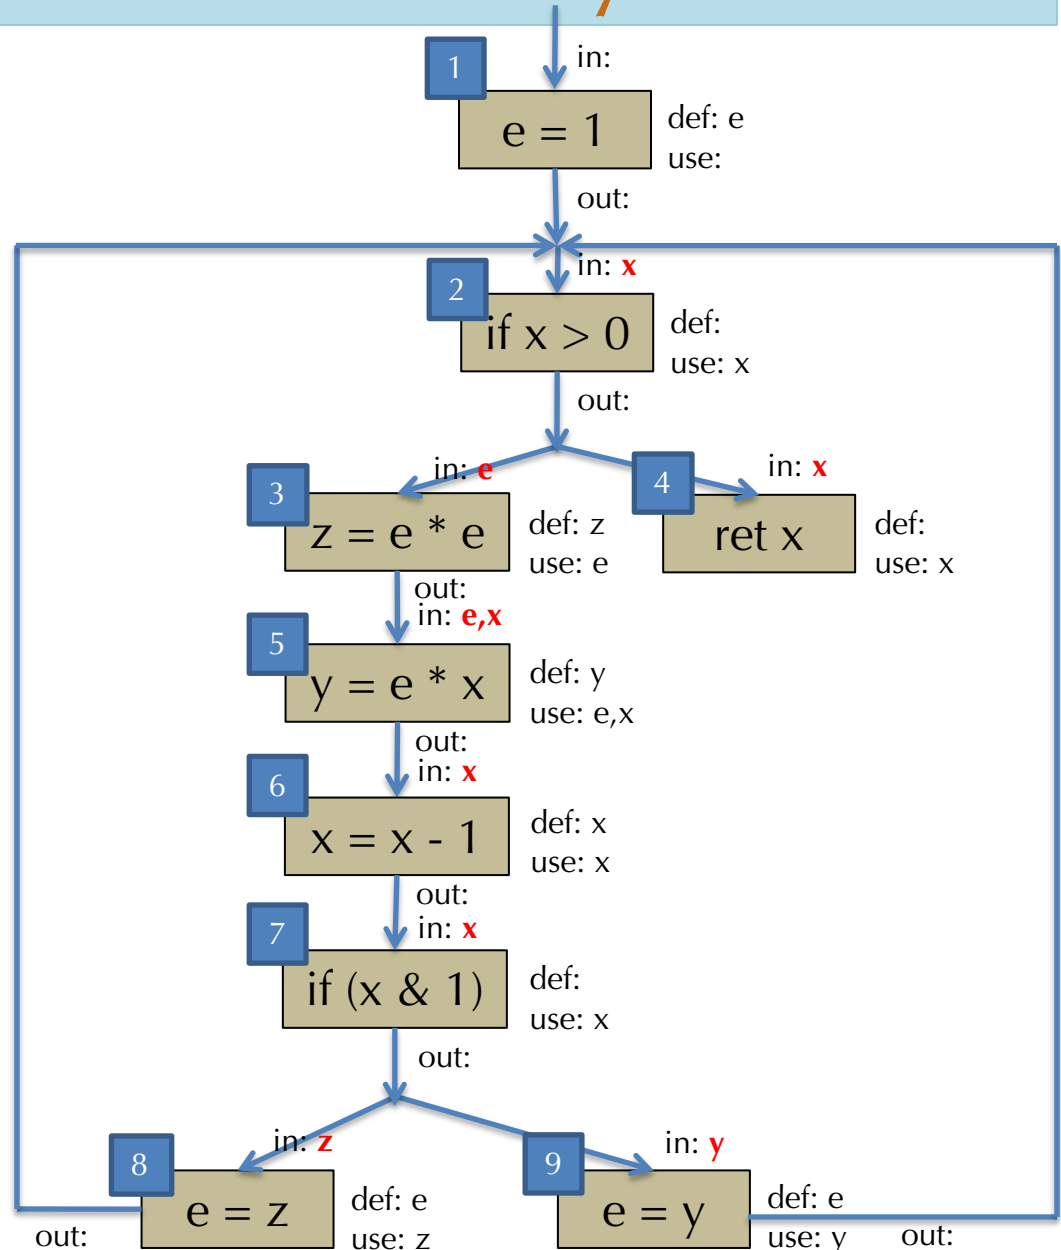

in[6] = x

in[7] = x

in[8] = z

in[9] = y

(showing only updates that make a change)

# Example Liveness Analysis

Each iteration update:

$$\text{out}[n] := \bigcup_{n' \in \text{succ}[n]} \text{in}[n']$$

$$\text{in}[n] := \text{use}[n] \cup (\text{out}[n] - \text{def}[n])$$

- Iteration 2:

$\text{out}[1] = x$

$\text{in}[1] = x$

$\text{out}[2] = e, x$

$\text{in}[2] = e, x$

$\text{out}[3] = e, x$

$\text{in}[3] = e, x$

$\text{out}[5] = x$

$\text{out}[6] = x$

$\text{out}[7] = z, y$

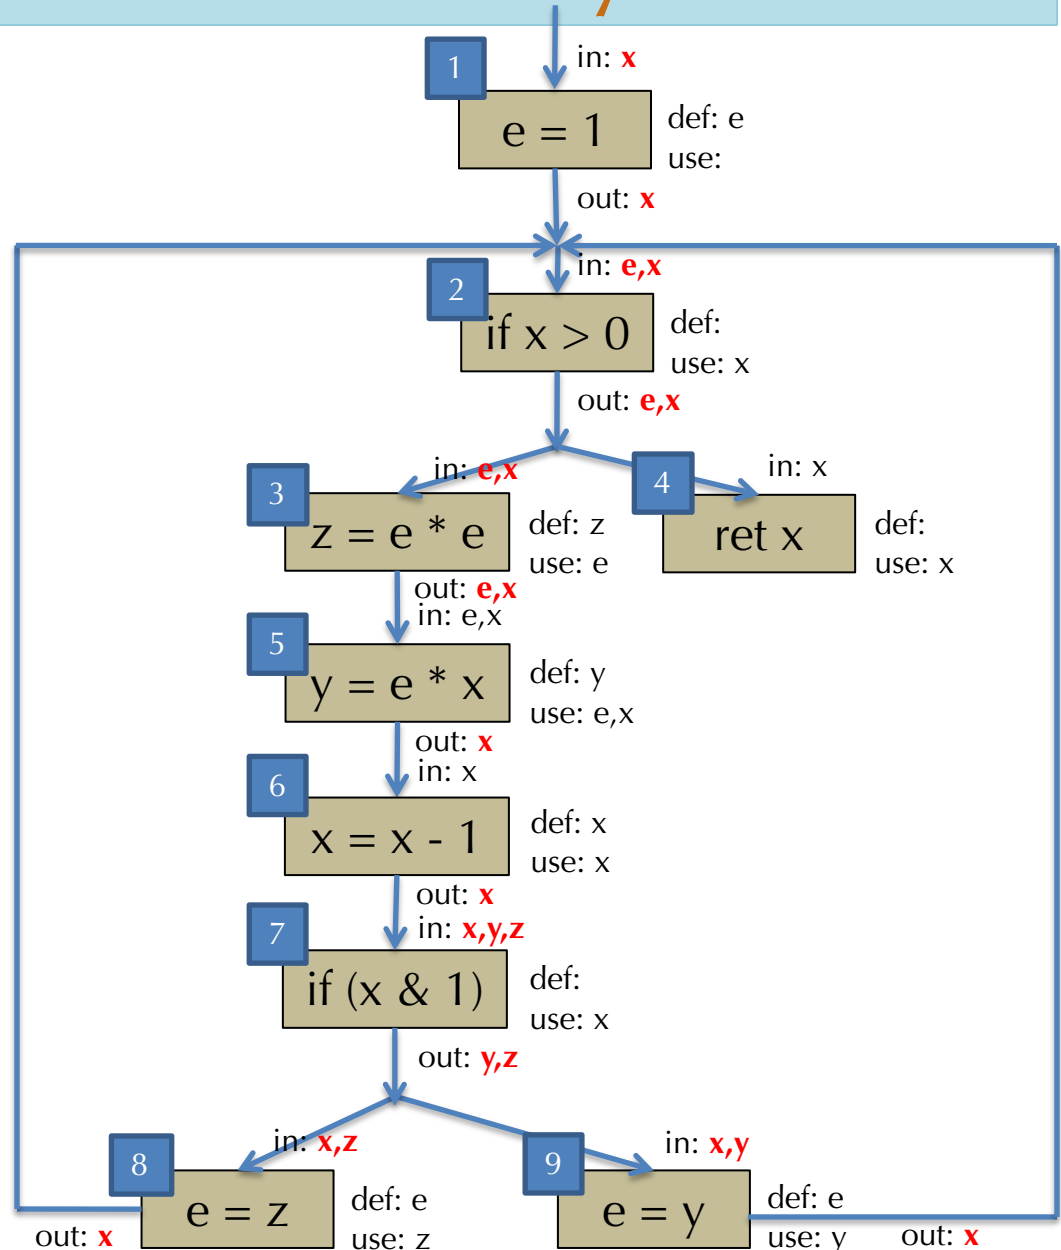

$\text{in}[7] = x, z, y$

$\text{out}[8] = x$

$\text{in}[8] = x, z$

$\text{out}[9] = x$

$\text{in}[9] = x, y$

# Example Liveness Analysis

Each iteration update:

$$\text{out}[n] := \bigcup_{n' \in \text{succ}[n]} \text{in}[n']$$

$$\text{in}[n] := \text{use}[n] \cup (\text{out}[n] - \text{def}[n])$$

- Iteration 3:

$\text{out}[1] = e, x$

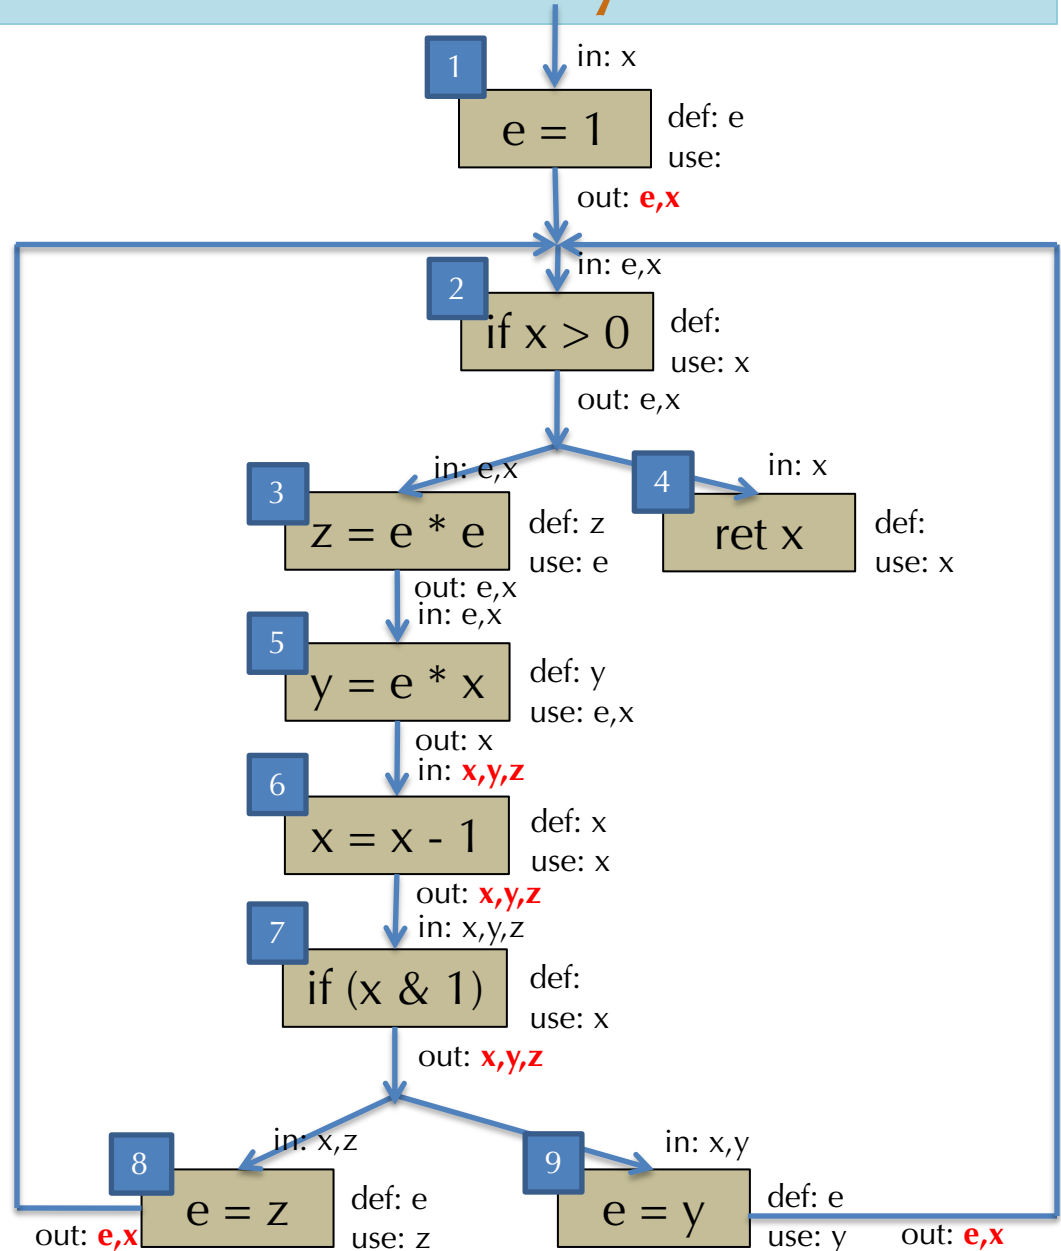

$\text{out}[6] = x, y, z$

$\text{in}[6] = x, y, z$

$\text{out}[7] = x, y, z$

$\text{out}[8] = e, x$

$\text{out}[9] = e, x$

# Example Liveness Analysis

Each iteration update:

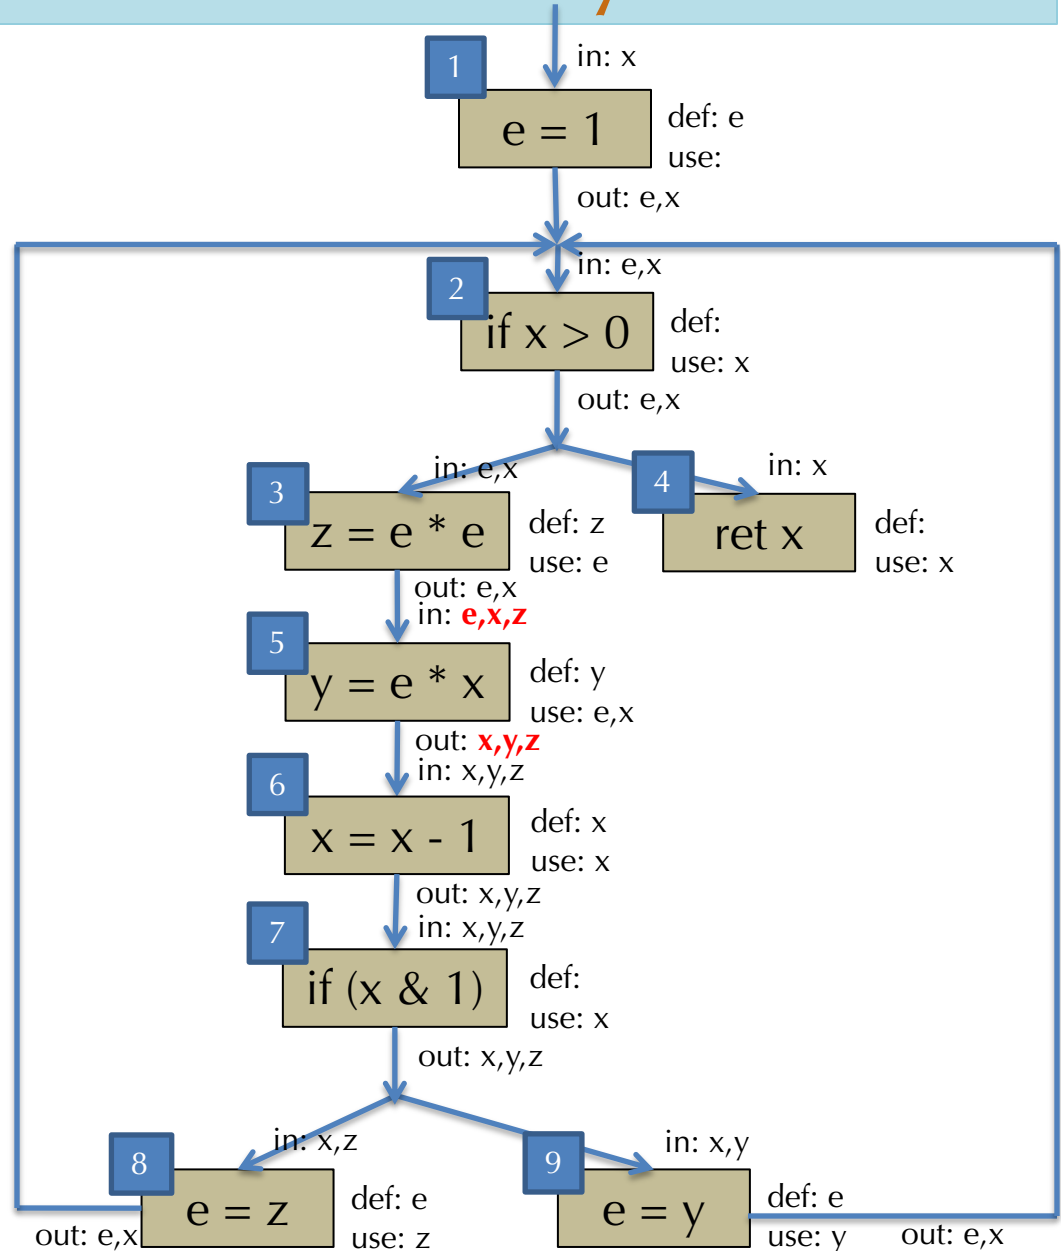

$$\text{out}[n] := \bigcup_{n' \in \text{succ}[n]} \text{in}[n']$$

$$\text{in}[n] := \text{use}[n] \cup (\text{out}[n] - \text{def}[n])$$

- Iteration 4:

$\text{out}[5] = x, y, z$

$\text{in}[5] = e, x, z$

# Example Liveness Analysis

Each iteration update:

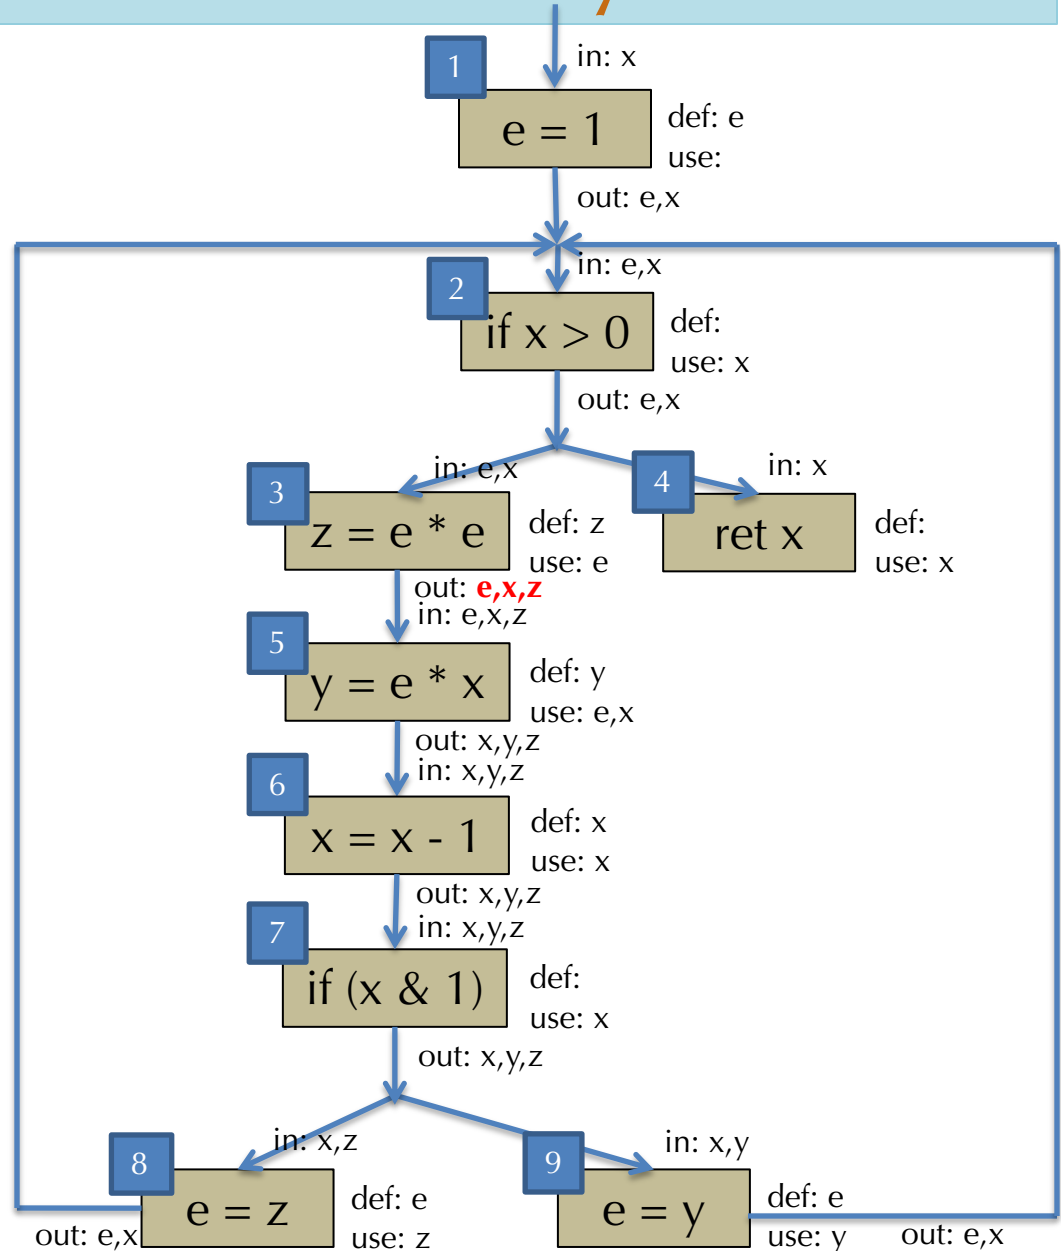

$$\text{out}[n] := \bigcup_{n' \in \text{succ}[n]} \text{in}[n']$$

$$\text{in}[n] := \text{use}[n] \cup (\text{out}[n] - \text{def}[n])$$

- Iteration 5:

$\text{out}[3] = e, x, z$

Done!

# Improving the Algorithm

- Can we do better?
- Observe: the only way information propagates from one node to another is using:  $\text{out}[n] := \bigcup_{n' \in \text{succ}[n]} \text{in}[n']$ 
  - This is the only rule that involves more than one node
- If a node's successors haven't changed, then the node itself won't change.
- Idea for an improved version of the algorithm:
  - Keep track of which node's successors have changed

# A Worklist Algorithm

- Use a FIFO queue of nodes that might need to be updated.

for all  $n$ ,  $\text{in}[n] := \emptyset$ ,  $\text{out}[n] := \emptyset$

$w$  = new queue with all nodes

repeat until  $w$  is empty

    let  $n = w.\text{pop}()$

*// pull a node off the queue*

$\text{old\_in} = \text{in}[n]$

*// remember old in[n]*

$\text{out}[n] := \bigcup_{n' \in \text{succ}[n]} \text{in}[n']$

$\text{in}[n] := \text{use}[n] \cup (\text{out}[n] - \text{def}[n])$

    if ( $\text{old\_in} \neq \text{in}[n]$ ),

*// if in[n] has changed*

        for all  $m$  in  $\text{pred}[n]$ ,  $w.\text{push}(m)$  *// add to worklist*

end

# **OTHER DATAFLOW ANALYSES**

# Generalizing Dataflow Analyses

- The kind of iterative constraint solving used for liveness analysis applies to other kinds of analyses as well.
  - Reaching definitions analysis
  - Available expressions analysis
  - Alias Analysis
  - Constant Propagation
  - These analyses follow the same 3-step approach as for liveness.
- To see these as an instance of the same kind of algorithm, the next few examples to work over a canonical intermediate instruction representation called *quadruples*
  - Allows easy definition of  $\text{def}[n]$  and  $\text{use}[n]$
  - A slightly “looser” variant of LLVM’s IR that doesn’t require the “static single assignment” – i.e. it has *mutable* local variables
  - We will use LLVM-IR-like syntax

# Quadruples

- A Quadruple sequence is just a control-flow graph (flowgraph) where each node is a quadruple:

Quadruple forms	n:	def[n]	use[n]	description
a = b op c		{a}	{b,c}	arithmetic
a = load b		{a}	{b}	load
store b, a		Ø	{b}	store
a = call f(b <sub>1</sub> ,...,b <sub>n</sub> )		{a}	{b <sub>1</sub> ,...,b <sub>n</sub> }	call w/return
call void f(b <sub>1</sub> ,...,b <sub>n</sub> )		Ø	{b <sub>1</sub> ,...,b <sub>n</sub> }	call no return
br L		Ø	Ø	direct jump
br a, L1, L2		Ø	{a}	branch
ret a		Ø	{a}	return

# REACHING DEFINITIONS

# Reaching Definition Analysis

- Question: what uses in a program does a given variable definition reach?
- This analysis is used for constant propagation & copy prop.
  - If only one definition reaches a particular use, can replace use by the definition (for constant propagation).
  - Copy propagation additionally requires that the copied value still has its same value – computed using an *available expressions* analysis (next)
- Input: Quadruple CFG
- Output: `in[n]` (resp. `out[n]`) is the set of nodes defining some variable such that the definition may reach the beginning (resp. end) of node n

# Example of Reaching Definitions

- Results of computing reaching definitions on this simple CFG:

# Reaching Definitions Step 1

- Define the sets of interest for the analysis
- Let  $\text{defs}[a]$  be the set of *nodes* that define the variable  $a$
- Define  $\text{gen}[n]$  and  $\text{kill}[n]$  as follows:

Quadruple forms $n$ :	$\text{gen}[n]$	$\text{kill}[n]$
$a = b \text{ op } c$	$\{n\}$	$\text{defs}[a] - \{n\}$
$a = \text{load } b$	$\{n\}$	$\text{defs}[a] - \{n\}$
$\text{store } b, a$	$\emptyset$	$\emptyset$
$a = f(b_1, \dots, b_n)$	$\{n\}$	$\text{defs}[a] - \{n\}$
$f(b_1, \dots, b_n)$	$\emptyset$	$\emptyset$
$\text{br } L$	$\emptyset$	$\emptyset$
$\text{br } a \text{ } L1 \text{ } L2$	$\emptyset$	$\emptyset$
$\text{return } a$	$\emptyset$	$\emptyset$

# Reaching Definitions Step 2

- Define the constraints that a reaching definitions solution must satisfy.
- $out[n] \supseteq gen[n]$   
“The definitions that reach the end of a node at least include the definitions generated by the node”
- $in[n] \supseteq out[n']$  if  $n'$  is in  $pred[n]$   
“The definitions that reach the beginning of a node include those that reach the exit of *any* predecessor”
- $out[n] \cup kill[n] \supseteq in[n]$   
“The definitions that come in to a node either reach the end of the node or are killed by it.”
  - Equivalently:  $out[n] \supseteq in[n] - kill[n]$

# Reaching Definitions Step 3

- Convert constraints to iterated update equations:
- $\text{in}[n] := \bigcup_{n' \in \text{pred}[n]} \text{out}[n']$
- $\text{out}[n] := \text{gen}[n] \cup (\text{in}[n] - \text{kill}[n])$
- Algorithm: initialize  $\text{in}[n]$  and  $\text{out}[n]$  to  $\emptyset$ 
  - Iterate the update equations until a fixed point is reached
- The algorithm terminates because  $\text{in}[n]$  and  $\text{out}[n]$  increase only *monotonically*
  - At most to a maximum set that includes all variables in the program
- The algorithm is precise because it finds the *smallest* sets that satisfy the constraints.
